Health Risk Assessment

Health Risk Assessment

for the

San José State University Santa Clara County Campus Master Plan

Prepared By:

Ascent Environmental

Prepared For:

San Jose State University

December 9, 2024

1 INTRODUCTION

This health risk assessment (HRA) evaluates the potential health risks associated with the construction and implementation of the proposed redevelopment projects in SJSU Master Plan (project) in the City of San Jose (City), located in Santa Clara County. The focus of this HRA is to evaluate the exposure of nearby residential receptors to project related toxic air contaminants (TACs), primarily diesel particulate matter (Diesel PM), from diesel-powered equipment and vehicles used during construction and the hauling of materials and emissions of fine particulate matter ($PM_{2.5}$), as well as the operational emissions associated with diesel PM from emergency back-up generators and the off-gassing emissions associated with use of various chemicals at laboratory uses. This study was conducted in accordance with BAAQMD's *Recommended Methods for Screening and Modeling Local Risks and Hazards* (*Recommended Methods*) (BAAQMD 2011) and BAAQMD's *Air Quality Guidelines Appendix E: Recommended Methods For Screening and Modeling Local Risks and Hazards* (BAAQMD 2022). Additionally, in preparing this HRA, procedures detailed in the California Office of Environmental Health Hazard Assessment's (OEHHA's) *Air Toxic Hot Spot Program Guidance Manual for Preparation of Health and Risk Assessments* (OEHHA 2015) were followed to quantify the potential health risks experienced by nearby receptors due to project-generated construction emissions. This report discusses the analysis methodology, thresholds of significance used, and the results of the HRA.

2 INVENTORY OF TOXIC AIR CONTAMINANT EMISSIONS

Construction-related emissions of diesel PM were determined by conducting detailed construction emissions modeling for the project using BAAQMD-recommended California Emissions Estimator Model (CalEEMod), version 2022.1. CalEEMod default values for equipment parameters (e.g., engine horsepower, number, type per phase) were used. Construction activities for the project would include demolition, site preparation, grading, building construction, and architectural coating. Construction is anticipated to begin in January of 2025 and would be complete by December of 2045, in four phases. $PM_{2.5}$ exhaust emissions would occur from diesel-powered heavy-duty construction equipment, diesel generators, and diesel trucks used during construction. To estimate risk, average daily and annual construction emissions of exhaust $PM_{2.5}$, used as a proxy for diesel PM, were computed.

The diesel PM emissions generated by off-site vehicle traffic (e.g., vendor and off-hauling trips) were modeled along several routes terminating at the Main Campus project site and one route terminating at the South Campus project site (see Section 3.3.3 for haul route details). This approach is realistic yet conservative because the construction projects spreading over the main campus makes one haul route impossible, and also because the potentially impacted residential buildings surround the main campus. Model defaults were used for worker, hauling, and vendor trips and trip lengths, based on the proposed project type/size. Heavy-duty equipment use would occur in areas where grading and new construction would occur. Emissions estimates from construction equipment and on-road truck trips are shown in Attachment A. In summary, the sources modeled for construction HRA were:

- Heavy-duty construction equipment diesel PM ($PM_{2.5}$ exhaust) emissions and dust from vehicle movement ($PM_{2.5}$ dust) as adjacent line volume sources, covering the project site where construction activities would occur;

- Construction worker and haul/vendor truck on-road emissions of diesel PM and fugitive dust on roadways as volume line sources;
- Onsite diesel PM idling emissions as point sources.

Operation related emissions of TACs primarily include diesel PM generated from running emergency diesel generators and other TACs evaporated from storage/use of laboratory chemicals. SJSU provided an annual inventory of all chemicals currently stored for each existing facility. The specific TACs analyzed in this HRA are based on the list provided in the Consolidated Table of OEHHA/CARB Approved Risk Assessment Health Values (Consolidated Table) (CARB 2023). Any substances in this table that did not have risk values were excluded from the analysis. SJSU provided these chemical inventories on the basis of the size and quantities of the containers of each chemical type. The metrics of these containers varied between volume and mass. Emission rates were estimated for each substance based on consolidated quantities and sorted by score of cancer potential factor multiplied by emission rate. The ten laboratory TACs with the highest scores were analyzed in this HRA. Emission estimates from generators and laboratory chemicals are shown in Attachment A. In summary, the sources modeled for operation HRA were:

- Emergency generator equipment diesel PM (exhaust $PM_{2.5}$) emissions as point sources;
- Lab hood exhaust emissions from building roofs modeled as area sources.

3 AIR DISPERSION MODELING

3.1 APPROACH

To determine health risk and pollutant concentrations at specific locations (i.e., receptors), first, air dispersion modeling was conducted using site-specific parameters (e.g., terrain, meteorological data), and then risk calculations were conducted. Dispersion modeling was conducted using the California Air Resource Board's (CARB's) approved American Meteorological Society/Environmental Protection Agency Regulatory Model Improvement Committee modeling system (AERMOD) Version 23132, with a unit emission rate of 1 gram per second (g/s) for all modeled sources. This approach is used so that resulting ground-level concentrations can be multiplied by actual emission rates for various scenarios (e.g., default model runs, reduced emissions scenario) without running AERMOD multiple times.

Then, using the ground-level concentrations from the AERMOD run at each receptor location in combination with emission estimates for $PM_{2.5}$, cancer risk and PM concentration calculations were conducted using cancer potency factors consistent with OEHHA guidance. The air dispersion model included all standard regulatory default options, including the use of urban dispersion parameters and local terrain. Terrain in the project vicinity is generally flat.

Land uses in the city include many multi-story and variable-size buildings, which results in urban flow patterns that are likely influenced by recirculation and channeling in urban canyons. The urban dispersion modeling parameters account for such patterns. The urban heat island effect, which results from surface heating of paved and built-up environment, is likely prevalent in some areas of the city and leads to longer periods of mixing and generally lower predicted air concentrations. AERMOD allows the user to model urban heat island impacts by selecting urban land use option. The SJSU campus fits the definition of an

urban area; thus, this land use option was used in the AERMOD dispersion runs to estimate air pollutant concentrations.

3.2 AERMOD MODEL CONFIGURATION

The following input parameters were used in the model run:

- Projected Coordinate System: Universal Transverse Mercator (UTM) zone 10;
- Geographic Datum: North American Datum 1983 (NAD83);
- Urban land use based on AERMOD's Land Use Procedure based on the level of development within a 3-kilometer (km) radius of the project site;
- Period (i.e., annual) averaging of concentrations for construction activity and operation;
- Unit emission rate of 1 g/s for all sources; and
- U.S. Geologic Survey North American Datum NAD 27 7.5-minute terrain data.

3.3 INPUTS AND ASSUMPTIONS

3.3.1 Meteorological Data

Pre-processed meteorological data from 2015-2017 collected at the San Jose International Airport Station were obtained from BAAQMD. The station is the nearest to the project site, located two miles northwest to the SJSU Main Campus, and therefore, the most representative meteorological station for the project site. The wind primarily blows from the west-northwest. Dispersion modeling applied a time-averaged, simplified representation of turbulent, atmospheric transport to approximate how pollutants are carried, mixed, dispersed, and diluted by the local winds.

3.3.2 Receptor Grid

Initially, a grid of 11,210 Cartesian receptors was established to encompass an area extending 1,150 meters from the boundaries of both Main and South Campus, as well as all the haul routes. After the preliminary run, the areas most significantly affected were identified through concentration contour plots for all sources. Subsequently, the receptor grid was refined to cover most impacted regions for the final analysis. The final configuration has a total of 5,289 discrete receptors spaced at 20-meter intervals. A total of 964 receptors were identified as residential receptors, including 31 receptors located at southeast corner of the Main Campus. All receptors were assigned a flagpole height of 1.5 meters to represent the average breathing height, following BAAQMD's Guidelines (BAAQMD, 2022).

3.3.3 Source Type and Dimensions

Construction and operational emission dispersion were modeled separately in AERMOD. All sources are defined with an emission rate of 1 g/s to generate unitized-emission concentration data that can be scaled later.

For construction emissions, a total number of 54 sources are defined, and grouped into 28 groups by phase and emission types. Construction emission types include onsite exhaust, haul truck exhaust, onsite idling exhaust, onsite fugitive dust, and haul truck fugitive dust.

The HRA follows the guidance within BAAQMD's Guidelines (BAAQMD 2022). For the project site where construction activities would occur, construction emission sources (i.e., the use of heavy-duty equipment on site) were modeled as adjacent line volume sources. Each volume source was modeled with a plume height of 2.6 m and plume width of 8.0 m. One set of volume sources were modeled with a release height of 0 m, representing ground-level dust emissions, and one set of volume sources with a release height of 1.3 m were modeled, representing diesel PM exhaust.

Haul routes were modeled using adjacent line volume sources. One set of volume sources were modeled with a release height of 0 m, representing dust emissions, and one set of volume sources with a release height of 3.4 m were modeled, representing diesel PM exhaust. The line sources represent the haul truck emissions traveling to and from the site. Plume width was 8.0 m and plume height was 6.8 m. The lengths of haul routes varied from 0.4 to 1.1 miles and were contingent on the specific campus and construction phase. These routes extended from Alquist Redevelopment site, Main Campus, and South Campus to Interstate Highway 280, along South 3rd, 4th, 7th, 10th, and 11th Streets.

A total of six point sources were used to model truck idling emissions onsite at two campuses during four construction phases, one at the Alquist site, four at the Main campus, and one at the south campus. Source parameters include 17.8 m/s exit velocity, 700 Kelvin gas exit temperature, release height of 3.4 m, and inside stack diameter of 0.305 m, consistent with recommendations for sources with incomplete modeling information from BAAQMD (BAAQMD 2022).

For operational emissions, a total of ten sources were defined for emergency generators and laboratory building. Emissions from emergency generators were modeled as individual point sources. One emergency generator was assumed for every two new large-scale structures (building size >200,000 gross square feet), which resulted in a total number of four generators on the Main Campus. These generators were modeled as enclosed outdoor generators with release height of 3.66 m, 872 Kelvin gas exit temperature, stack inside diameter of 0.183 m, and gas exit velocity of 45.3 m/s, consistent with the default parameters for prime or standby generator recommended in BAAQMD guide (BAAQMD 2022).

Laboratories store and actively use a variety of chemicals that can become airborne through chemical evaporative losses during storage and normal chemical handling. Many of these chemicals are considered TACs by OEHHA. A total number of six new buildings are identified to have laboratories. There are multiple exhausts on the roof of each building. Laboratory-related emissions from each building were modeled as individual area sources, with a stack height of 10 feet, as specific building configurations and fume hood locations are unknown at the programmatic level of analyses conducted. Source locations, group, and haul routes are shown in Attachment A.

4 HEALTH RISK CALCULATIONS

4.1 CANCER AND NON-CANCER RISK

To analyze impacts to sensitive receptors, the resulting pollutant concentrations from the AERMOD dispersion analysis were multiplied by the emission rates to obtain risk estimates.

Total annual tons of exhaust $PM_{2.5}$ emissions resulting from project construction were converted to grams per second, based on the anticipated duration of each construction phases and a Monday through Friday work week with 12-hour work days. Estimated emission rates for each diesel PM source (i.e., onsite equipment , onsite idling, offsite hauling) were multiplied by the unitized AERMOD outputs for their respective source type to obtain scaled concentrations of diesel PM. Risk calculations were conducted using the following parameters, consistent with OEEHA guidance, shown in Table 1. All risk calculations are included in Attachment A.

Table 1 Risk Parameters for Cancer and Non-Cancer Risk[1]

Risk Parameters	Construction	Operations
Analysis Type	Cancer Risk and Chronic Risk (Non-cancer)	Cancer Risk and Chronic Risk (Non-cancer)
Receptor Type	Residential	Residential
Exposure Duration	22 years	30 years
Averaging Time	70 years	70 years
Starting Age	3rd Trimester	3rd Trimester
FAH	1.0 for <16 years old, 0.7 for 16-30 years old	1.0 for <16 years old 0.7 for 16-30 years old

[1] Analysis was prepared consistent with OEHHA Guidance (OEHHA 2015).

Notes: OEHHA = Office of Environmental Health Hazard Assessment; FAH = fraction of time at home

Source: Prepared by Ascent in 2024

4.2 ANNUAL AVERAGE $PM_{2.5}$ CONCENTRATIONS

In addition to cancer and non-cancer health risks resulting from exposure to diesel PM TAC emissions, potential impacts from $PM_{2.5}$ construction emissions were evaluated. The same basic modeling approach that was used for assessing health risks was used in the modeling of $PM_{2.5}$ concentrations. Both exhaust and fugitive $PM_{2.5}$ emissions were included. Dispersion modeling of $PM_{2.5}$ using the AERMOD model was conducted in the same manner as the TAC modeling. The model predicted the annual average $PM_{2.5}$ concentrations.

Project emission dust ($PM_{2.5}$ fugitive) and diesel PM ($PM_{2.5}$ exhaust) for each source (i.e., onsite equipment use, onsite idling, offsite hauling) were multiplied by the unitized AERMOD outputs for their respective source type to obtain scaled concentrations of $PM_{2.5}$, then dust and exhaust $PM_{2.5}$ scaled concentrations were summed together to obtain the total PM2.5 concentrations.

5 HEALTH RISK CEQA THRESHOLDS OF SIGNIFICANCE

According to BAAQMD, a project's impact on health risks would be considered significant under the California Environmental Quality Act (CEQA) if the project-related increase in risks would exceed the following thresholds shown in Table 2. Results of this HRA are compared to the BAAQMD-adopted thresholds of significance.

Table 2 Significant Health Risk Levels

	Significance Risk Threshold
Maximum Incremental Cancer Risk[1]	10.0 chances in a million
Total Chronic Non-Cancer Health Hazard Index[2]	1.0
Incremental Annual Average $PM_{2.5}$ Concentration[3]	Ambient $PM_{2.5}$ increase: >0.3 µg/m^3

1. Maximum Incremental Cancer Risk is the maximum lifetime excess cancer risk estimate (per million) at residential or worker receptor (whichever is greater). The maximum estimated risk generally is possible at only one location. All other locations show lower risks. Actual cancer risk would likely be less.
2. Total Chronic Health Hazard Index (HIC) is the sum of the ratios of the average annual exposure level of each compound to the compound's Reference Exposure Level (REL). Actual HIC would likely be less.
3. An incremental increase of greater than 0.3 micrograms per cubic meter (µg/m^3) annual average $PM_{2.5}$ would be a cumulatively considerable contribution

Source: BAAQMD 2022

6 RESULTS

6.1 HRA RESULT FOR CONSTRUCTION AND OPERATION

Based on CalEEMod model defaults, air dispersion modeling and risk calculations discussed above, project-generated maximum incremental cancer risks, noncancer chronic health hazard indexes, and incremental annual average $PM_{2.5}$ concentrations are summarized in Table 3 for construction, operation, and the combined construction and operation scenarios. Similarly, HRA were conducted for mitigated scenario (Tier 4 engine implemented for all heavy-duty construction equipment and emergency generators), and summarized in Table 4.

Considering BAAQMD threshold of significance of 10 chances in a million for cancer risk and a non-cancer health index threshold of less than 1.0, the unmitigated construction would result in above-threshold cancer risks for Phase 1 construction, total construction, operation, and construction + operation scenarios, and below-threshold chronic hazard indexes and $PM_{2.5}$ concentrations for all scenarios, as shown in Table 3. The cancer risk due to exposure to construction emissions could be lowered to below threshold with Tier 4 Engine standard implemented on all heavy-duty construction equipment, as shown in Table 4. Figure 1 in Attachment A graphically depicts the cancer risk at nearby receptors as colored contours radiating outward from the project site, including the PMI and the maximally exposed individual receptors (MEIRs).

Additionally, based on dispersion modeling conducted, the annual average increase in ambient $PM_{2.5}$ concentration in the project vicinity during construction does not exceed the BAAQMD's $PM_{2.5}$ annual average concentration threshold of 0.3 µg/m^3. The increase in ambient $PM_{2.5}$ concentration during operation would exceed the BAAQMD threshold. With mitigation measure of Tier 4 Engines for all

emergency generators, the increased $PM_{2.5}$ ambient concentration can be lowered to below threshold, shown in Table 3 and Table 4. Note that the mitigation applied in this HRA assumed all Tier 4 engines for operations; however, as shown in Section 3.2 of the EIR, "Air Quality," further mitigation was applied to eliminate the use of diesel-powered generators, further reducing risk and $PM_{2.5}$ emissions, to below applicable thresholds.

Table 3 DPM and PM2.5 HRA Result Summary, Unmitigated

Phases[1]	MEIR Receptor ID	Maximum Incremental Cancer Risk (1/million)	Chronic Hazard Index	$PM_{2.5}$ Concentration ($\mu g/m^3$)	Location (x, y)
Phase 1	2671	7.8	0.002	0.047	599278.57, 4132471.6
Phase 2	2780	4.2	0.003	0.077	599358.57, 4132511.6
Phase 3	2882	2.2	0.002	0.047	599178.57, 4132551.6
Phase 4	3446	0.2	0.002	0.069	599378.57, 4132751.6
Total Construction[2]	2780	12.0	0.003	0.077	599378.57, 4132471.6
Operations[3]	3669	8.5	0.002	0.011	599398.57, 4132471.6

1. Phases of construction: Phase 1=Year 2025– 2029; Phase 2=2030– 2034; Phase 3=2035– 2039; Phase 4=2040– 2045.
2. Exposure duration during construction is 22 years, starting at 3rd trimester.
3. Exposure duration during operations is 30 years, starting at 3rd trimester.
4. Exposure duration = 22 years of construction years + 30 years of operation at each receptor.

Table 4 DPM and PM2.5 HRA Result Summary, Mitigated

Phases[1]	MEIR Receptor ID	Maximum Incremental Cancer Risk (1/million)	Chronic Hazard Index	$PM_{2.5}$ Concentration ($\mu g/m^3$)	Location (x, y)
Phase 1	2671	0.9	<0.001	<0.001	599278.57, 4132471.6
Phase 2	2780	0.7	<0.001	<0.001	599358.57, 4132511.6
Phase 3	2780	0.5	<0.001	<0.001	599358.57, 4132511.6
Phase 4	3820	0.04	<0.001	<0.001	599238.57, 4132931.6
Total Construction[2]	2779	1.9	<0.001	0.056	599378.57, 4132471.6
Operations[3]	3669	2.1	<0.001	0.003	599398.57, 4132471.6
Construction +Operations[4]	2779	3.7	<0.001	0.056	599398.57, 4132471.6

1. Phases of construction: Phase 1=Year 2025– 2029; Phase 2=2030– 2034; Phase 3=2035– 2039; Phase 4=2040– 2045.
2. Exposure duration during construction is 22 years, starting at 3rd trimester.
3. Exposure duration during operation is 30 years, starting at 3rd trimester.
4. Exposure duration = 22 years of construction + 30 years of operation at each receptor.

6.2 LABORATORY TACS EMISSIONS

The lifetime cancer risk associated with the laboratory TAC emissions is estimated to be 0.249 chances in a million, as shown in Table 5. Considering BAAQMD threshold of significance of 10 chances in a million for cancer risk, this level of risk does not exceed the applicable threshold. Chronic hazard exposure to any of the TACs would not exceed the 1.0 threshold.

Table 5 HRA result for Top 10 TACs Emissions from Laboratories

TACs	Cancer Risk (1 chance in a million)	Chronic Health Hazard Index
Chromic Acid	0.192	0.001
Carbon tetrachloride	0.013	<0.001
Benzene	0.003	<0.001
1,4-Dichlorobenzene	0.003	<0.001
Chloroform, stabilized	0.001	<0.001
Dichloromethane, stabilized	0.001	<0.001
Naphthalene	<0.001	<0.001
Propylene oxide	<0.001	<0.001
p-Dioxane	<0.001	<0.001
Formaldehyde	<0.001	<0.001
Combined Risk from All TACs	**0.212**	**0.001**

Source: Prepared by Ascent in 2024.

6.3 COMBINED RISK FROM DPM AND LABORATORY TAC EMISSIONS

The combined risk from construction and operations during both construction and operations is summarized in Table 6. As shown, the combined risk is estimated to reduce from 19.6 chances in a million under the unmitigated scenario to 3.7 chances in a million under the mitigated scenario. As such, this level of risk is expected to be below the applicable threshold of 10 chances in a million for cancer risk. Risk is below the chronic hazard and $PM_{2.5}$ threshold under the under the mitigated scenario.

Table 6 Summary of HRA from Combined Construction and Operations

Risk Source	MEIR Receptor ID	Unmitigated Maximum Incremental Cancer Risk (1/million)	Mitigated Maximum Incremental Cancer Risk (1/million)
Construction DPM	2780	12.0	1.9
Operations DPM	3669	8.5	2.1
Operations Laboratory TACs	3281	0.2	0.2
Total Risk	**2780**	**19.6**	**3.7**

Note that because the MEIR location is different for each component, the risk is not additive since the MEIR occurs at different locations depending on the risk source.

4	400	0.0219538	0.0007554	0.018084567	0.00466031	8.22E-4

Notes:

The total haul emissions were multiplied by a factor of L/Lo to estimate haul emissions withing the project impact area.

L/Lo = 10% Trip length ratio for hauling

L = 2 miles, Trip length within project impact area

Lo = 20 miles, one-way haul trip length, CalEEMod default

Haul Split:

IDLE 15% assumed percentage of haul truck emission due to idling

Each phase has various workdays for concurrent construction at Main campus, South campus, and Alquist Redevelopment site. The number of workdays for each phase is based on construction intensity at each location: Phase 1 workdays used Alquist Redevelopment workdays; Phase 2, 3, 4 workdays used Main Campus Workdays. L is conservatively estimated as the diagonal distance of the impact region of Main campus and South campus combined.

Emission Rate Adjusted, Unmitigated

Phases	PM2.5 Construction Emission rate (g/s)					PM2.5 Operation Emissions (g/s)
	Onroad Dust	Onroad Exhaust	Onsite Dust	Onsite Exhaust	Idling	Generator Exhaust
1	2.05E-4	7.96E-6	2.26E-4	1.72E-4	3.03E-5	0.00E+0
2	1.23E-4	3.55E-6	2.16E-4	9.51E-5	4.20E-5	2.04E-2
3	1.00E-4	2.78E-6	4.03E-4	1.17E-4	2.06E-5	2.04E-2
4	1.44E-4	4.96E-6	2.37E-4	6.12E-5	1.08E-5	2.04E-2
Operation 2045 (full buildout)						2.04E-2

Note: Adjusted emission rate = emission rate / number of sources for each phase and emission type.
